Resumo:

Nesse trabalho é apresentada uma metodologia para a detecção automática de nuvem e sombra de nuvem em imagens de sensores que atuam na faixa do visível e do infravermelho próximo. O trabalho visa à detecção em imagens do sensor AWFI que estará a bordo do satélite AMAZONIA-1. O método de detecção de nuvem é baseado na análise da detecção de filtros. Valores de NDVI, VI

Abstract. Cloud contamination can compromise surface observation on satellite images and impossibility land cover and land use mapping, due to their high reflectance. Similarly, cloud shadows can darken the image or be confused with water, making it harder to differentiate targets. This paper aims at evaluating an automatic cloud and cloud shadow detection method using decision tree classifier for CBERS-4 (China Brazil Earth Resources Satellite) MUX (Multispectral Camera) camera. In relation to the features used in the classification process, 3 methods were tested to classify 10 images of CBERS-4 MUX camera. The first one used spectral information and spectral indices, such as NDVI, WI and HOT; the second one added shape attributes in the feature set, and the third one added texture attributes. The classification process considered 3 classes: cloud, cloud shadow and cloud-free, which were validated using visually interpreted images. The results presented an overall accuracy of about 92.98%. The accuracy for the cloud detection was 0.91, while for the cloud shadow the classification accuracy was 0.67. These results point out that for sensors that has only visible and near infrared spectral bands, like CBERS-4/MUX, the NDVI, WI and HOT spectral indices are relevant for cloud detection. On the other hand, for cloud shadow detection it is necessary to explore other features capable to discriminate it from dark objects in the images.

New cloud probability

ABSTRACT

We developed the Function of mask (Fmask) 4.0 algorithm for automated cloud and cloud shadow detection in Landsats 4–8 and Sentinel-2 images. Three major innovative improvements were made as follows: (1) integration of auxiliary data, where Global Surface Water Occurrence (GSWO) data was used to improve the separation of land and water, and a global Digital Elevation Model (DEM) was used to normalize thermal and cirrus bands; (2) development of new cloud probabilities, in which a Haze Optimized Transformation (HOT)-based cloud probability was designed to replace temperature probability for Sentinel-2 images, and cloud probabilities were combined and re-calibrated for different sensors against a global reference dataset; and (3) utilization of spectral-contextual features, where a Spectral-Contextual Snow Index (SCSI) was created for better distinguishing snow/ice from clouds in polar regions, and a morphology-based approach was applied to reduce the commission error in bright land surfaces (e.g., urban/built-up and mountain snow/ice). The Fmask 4.0 algorithm showed higher overall accuracies for Landsats 4–8 imagery than the 3.3 version (Zhu et al., 2015) (92.40% versus 90.73% for Landsats 4–7 and 94.59% versus 93.30% for Landsat 8), and much higher overall accuracies for Sentinel-2 imagery than the 2.5.5 version of the Sen2Cor algorithm (Müller-Wilm et al., 2018) (94.30% versus 87.10%).

1. Introduction

Moderate spatial resolution images (10 to 30 m) from Landsats 4–8 and Sentinel-2 provide a great opportunity for monitoring global en-

vironmental changes. Multitemporal algorithms are particularly popular after the free policy of Landsat and Sentinel-2 (Frantz et al., 2015; Goodwin et al., 2013; Hagolle et al., 2010; Wang et al., 1999; Zhu and Helmer, 2018; Zhu and Woodcock, 2014). As the presence of cloud and cloud shadow will lead
